A small percentage of patients were administered drugs from all medication groups: hospice 17%, community 13% and hospital 4%. The number of patients administered drugs from each category varied across care setting but more patients required benzodiazepines and opioids compared to anti-secretories or anti-emetics.

**Conclusion** The use of anticipatory medication varies across care settings. This may be related to the average complexity of patient in each care setting. Universally there are trends in which groups of medications are used more/less often with opioids and benzodiazepines more commonly administered. Limitations include missing data and only recording medication use in the last three days of life; we will collect data for the last week of life in a repeat audit. Further community data is needed to guide a regional review including number of doses required and what medications were left at home following death.

### Results

1. To gain insight into the scale of prescribing of octreotide for inoperable malignant bowel obstruction in a tertiary cancer centre.
2. To compare the prescribing practices for octreotide in inoperable malignant bowel obstruction to those outlined in the local and national guidance.

**Methods** A retrospective audit of the electronic notes and online prescriptions for inpatients prescribed octreotide for inoperable malignant bowel obstruction over a one-year period. A total of 17 patients.

**Audit standards:**
1. The patient has been prescribed hyoscine butyl bromide prior to being prescribed octreotide.
2. The patient has been started on a dose of octreotide between 300–600 mcg/24hrs.
3. The patient has not been prescribed a dose of octreotide greater than 1500 mcg/24hrs.
4. The patient has a clearly documented indication for the use of octreotide.

**Conclusions** There are relatively few prescriptions for octreotide despite the audit data coming from a large cancer centre. Prescriptions generally follow the guidelines however documentation of indication and reason for divergence from the guideline needs improving.

**Recommendations** Consider using standardised documentation for when starting octreotide including indication, other medications concurrently prescribed, dietician involvement and NG tube placement.

### A CLINICAL AUDIT OF USE OF OCTREOTIDE IN THE MANAGEMENT OF INOPERABLE MALIGNANT BOWEL OBSTRUCTION AT A LARGE CANCER CENTRE

*Jennifer Palfrey, Vardana Vora. Guy’s and St Thomas’ Hospital*

**Abstract**

**Background** Octreotide is a somatostatin analogue used to reduce gastric and intestinal secretions therefore helping to improve symptoms of nausea and vomiting. There is mixed evidence for the use of octreotide however in both local guidelines and the Palliative Care Formulary it is considered second line for the treatment of vomiting and managing secretions in malignant bowel obstruction with hyoscine butylbromide as first line.

**Objectives**
1. To gain insight into the scale of prescribing of octreotide for inoperable malignant bowel obstruction in a tertiary cancer centre.
2. To compare the prescribing practices for octreotide in inoperable malignant bowel obstruction to those outlined in the local and national guidance.

**Methods** A retrospective audit of the electronic notes and online prescriptions for inpatients prescribed octreotide for inoperable malignant bowel obstruction over a one-year period. A total of 17 patients.

**Audit standards:**
1. The patient has been prescribed hyoscine butyl bromide prior to being prescribed octreotide.
2. The patient has been started on a dose of octreotide between 300–600 mcg/24hrs.
3. The patient has not been prescribed a dose of octreotide greater than 1500 mcg/24hrs.
4. The patient has a clearly documented indication for the use of octreotide.

**Results**
- Only 41% patients had hyoscine butyl bromide prescribed prior to being prescribed octreotide.
- 100% patients received the recommended starting dose of octreotide.
- No patients received octreotide received a dose greater than 1500 mcg/24hrs.
- 71% patients had a specific indication documented in the notes.

**Conclusions** There are relatively few prescriptions for octreotide despite the audit data coming from a large cancer centre. Prescriptions generally follow the guidelines however documentation of indication and reason for divergence from the guideline needs improving.

**Recommendations** Consider using standardised documentation for when starting octreotide including indication, other medications concurrently prescribed, dietician involvement and NG tube placement.
Methods Data regarding naloxone prescribing was obtained for two three-month periods; prior to and following the introduction of a prescribing order set which included guidance on the indications for naloxone use and appropriate doses. The notes of all patients who received naloxone in any time period were reviewed; and only patients prescribed long term opioids for pain were included in the audit. Data collected included age, sex, type and dose of opioid, equivalent doses of oral morphine per day, dose of naloxone administered, stated indication for use, respiratory rate, oxygen saturations and time to death where applicable.

Results Prior to the intervention 15 patients were identified. All of these received inappropriately high doses of naloxone. Following the intervention, the number of patients reduced by more than 50% (n=7), however all patients still received inappropriately doses. Worryingly there were no patients in either time period who had documented evidence of respiratory depression; most clinicians cited reduced level of consciousness as the reason for administering the drug.

Conclusion This intervention may have reduced the number of inappropriate prescriptions of naloxone in this subset of patients. However, more education is required to improve knowledge around the appropriate use of this potentially harmful drug. Future training sessions are planned to include staff from the emergency department and acute medicine.

Results

12 infusions were given to 10 patients. 4 were inpatients, the remainder day cases. Mild extravasation occurred in one case, leading to discolouration but no pain. There were no other adverse reactions. 30, 60 and 90-day survival was 92%, 92% and 58% respectively. Baseline haemoglobin was 80 g/L in 6 cases, 80–100 in 3 and >100 in 3. All met recommended criteria for diagnosing iron deficiency in cancer (ferritin <100μg/L and transferrin saturation <20%). Fatigue was documented for all, alongside breathlessness in 4 and bleeding in 2. 6 patients had received transfusions within the previous 3 months. Iron was given alone in 8 cases, none required subsequent transfusion. Transfusion was performed in addition to the iron infusion in 4 cases, 3 requiring further transfusions, although two had apparently decreased frequency to previously.

Conclusion This case series demonstrates the feasibility of using intravenous iron, within its product specification, to treat iron deficiency anaemia in a hospice setting. Research is required to confirm the efficacy and optimum targeting of this approach in palliative care populations.

Background Aim Polypharmacy, which refers to taking several medications concurrently, is often appropriate for children and young people (CYP) with life-limiting conditions (LLCs) but can increase the risk of drug-drug and drug-disease interactions, medication errors and non-adherence, and cause unnecessary burden for families as they manage complex medication schedules. Despite this, little is known about polypharmacy in this population. This study aims to determine the prevalence of polypharmacy in CYP with LLCs.

Methods An observational cohort study of all CYP (age 0–19 years) with a diagnosed LLC in the Clinical Practice Research Datalink (primary care dataset in England) from 2000 to 2015 (n=15,630). Unique prescriptions were identified and common definitions of polypharmacy were used to determine the prevalence in each year for all medications and for regular medications (those with at least 3 prescriptions in a 12 month period). Regression analyses were used to explore factors associated with an increased risk of polypharmacy.

Results In each year, approximately 30% of CYP were prescribed at least 5 unique medications, and 10% were prescribed at least 10 (median annual average=2, range=0–52). When limiting polypharmacy to regular medications, 29% were prescribed at least 2 medications per year, and 14% were prescribed at least 4. Children with a primary respiratory, neurological, metabolic or circulatory diagnosis were at the greatest risk of polypharmacy. Having a second LLC or other co-morbidity were also risk factors. The proportion of children exposed to polypharmacy remained similar throughout the study period.

Conclusion This ongoing study shows that CYP with LLCs are exposed to high rates of polypharmacy. Workshops with families and clinicians held as part of the study revealed that primary care data are likely to underestimate polypharmacy in this population, and allow for limited exploration of important factors that influence their exposure to inappropriate polypharmacy.

Background Xerostomia is the subjective experience of oral dryness and is reported in up to 88% of advanced cancer patients. Despite use of mouthwashes, artificial saliva and
