Hospice care access inequalities: a systematic review and narrative synthesis

Jake Tobin,1 Alice Rogers,1 Isaac Winterburn,2 Sebastian Tullie,1 Asanish Kalyanasundaram,1 Isla Kuhn,3 Stephen Barclay 2

ABSTRACT

Background Inequalities in access to hospice care is a source of considerable concern; white, middle-class, middle-aged patients with cancer have traditionally been over-represented in hospice populations.

Objective To identify from the literature the demographic characteristics of those who access hospice care more often, focusing on: diagnosis, age, gender, marital status, ethnicity, geography and socioeconomic status.

Design Systematic literature review and narrative synthesis.

Method Searches of Medline, PsycINFO, CINAHL, Web of Science, Assia and Embase databases from January 1987 to end September 2019 were conducted. Inclusion criteria were peer-reviewed studies of adult patients in the UK, Australia, New Zealand and Canada, receiving inpatient, day, outpatient and community hospice care. Of the 45,937 titles retrieved, 130 met the inclusion criteria. Narrative synthesis of extracted data was conducted.

Results An extensive literature search demonstrates persistent inequalities in hospice care provision: patients without cancer, the oldest old, ethnic minorities and those living in rural or deprived areas are under-represented in hospice populations. The effect of gender and marital status is inconsistent. There is a limited literature concerning hospice service access for the LGBTQ+ community, homeless people and those living with HIV/AIDS, diabetes and cystic fibrosis.

Conclusion Barriers of prognostic uncertainty, institutional cultures, particular needs of certain groups and lack of public awareness of hospice services remain substantial challenges to the hospice movement in ensuring equitable access for all.

INTRODUCTION

When the modern hospice movement started in 1967 with Dame Cicely Saunders opening St. Christopher’s Hospice in South London, the main focus of the early hospices was on excellence in the holistic palliative and end-of-life care of patients with cancer. Since those early days, hospices have sought to broaden their reach to include those with non-cancer diagnoses and other underserved groups.

In addition to inpatient beds, hospice care commonly includes specialist home care and community teams, Macmillan and Marie Curie nursing services, hospice at home services, day therapy and outpatient consultations. Working alongside colleagues in General Practice and District Nursing and hospital Palliative Care...
teams, hospices are often leaders in education and local service developments.

However, inequalities of hospice provision persist. Of the 528,973 deaths in England and Wales in 2019, 71.5% (378,108) were from non-cancer conditions and 28.5% (150,865) from cancer. Hospices were the place of death for 1.2% (4,503) of non-cancer deaths and 16.5% (24,925) of cancer deaths. Of the 29,428 deaths in hospices in 2019, 24,925 (84.7%) were from cancer and 4,503 (15.3%) from non-cancer. While many more people receive hospice care than die there, these figures suggest that patients with cancer remain disproportionately served by hospice care. National mortality statistics from Scotland and Northern Ireland are very similar.

Over recent years there has been growing recognition of the palliative care needs of people dying from non-cancer conditions, alongside the development of palliative care teams in hospitals and the community. While the proportion of non-cancer deaths occurring in hospice in England and Wales has increased over the past decade, from 7.8% in 2010 to 12.4% in 2015 and 15.3% in 2019, patients without cancer remain under-represented in these data.

Diagnosis is not the only inequality that persists in hospice care provision; evidence suggests that the oldest old (aged 85+) are also under-represented, alongside considerable disparities across geographical regions of the UK. To address these issues, there has been an impetus in many countries to improve the equity of palliative and end of life care provision. The 2008 UK Department of Health ‘End of Life Care Strategy’ promoted a ‘vision for a good death’ that is ‘irrespective of age, gender, ethnicity, religious belief, disability, sexual orientation, diagnosis or socioeconomic status’. This was echoed in the 2015 ‘Ambitions for Palliative and End of Life Care’, which emphasised that each person should have ‘fair access to care’.

We therefore undertook a systematic review of the literature to investigate the characteristics of those who access hospice services, focusing on the evidence concerning the presence and nature of any inequalities. In contrast to a 2013 rapid review focused on the UK literature between 2010 and 2015, we undertook a systematic review of the literature from 1987 to 2019 and included studies from the UK, Canada, Australia and New Zealand.

Aims
To systematically review and synthesise the peer-reviewed literature concerning referral to or receipt of hospice care with regards to eight characteristics: diagnosis and comorbid conditions; age; gender and sexuality; marital status; ethnicity and religion; geographical factors including rurality and distance to hospice; socioeconomic factors; other characteristics.

⇒ (specialist palliative care OR hospice OR "Hospice Care" OR "Hospices"")
```

METHODS
Following an initial scoping search, inclusion and exclusion criteria were clarified and search strategies developed in discussion with the review team’s Information Scientist (IK). Searches were undertaken for papers published between January 1987 (when Palliative Medicine became a recognised medical specialty in the UK) and the end of September 2019 in six databases: Medline, Embase and PsycINFO via OVID; CINAHL via EbscoHOST; ASSIA via Proquest; Web of Science. Additional searches included hand searches of Palliative Medicine and Journal of Palliative Care and reference and citation searches of included papers. Box 1 shows the PubMed search strategy.

Inclusion and exclusion criteria
Hospice care was broadly defined to include inpatient units and beds, day therapy, outpatients, hospice at home, community hospice teams, Macmillan and Marie Curie nurses, hospice chaplains and hospice social workers. Studies on deaths in hospice and referral to hospice services were included. Where studies included ‘hospice’ under a broader heading of ‘specialist palliative care’, they were included to ensure comprehensiveness. We restricted studies to those from countries with similar models of hospice care and health service provision: UK, Canada, Australia and New Zealand.

Publications were restricted to peer-reviewed journal papers, published in English and presenting new empirical data. Opinion pieces and editorials were excluded unless they contained original empirical data. Conference abstracts were included unless their data were subsequently published in full. The grey literature was not included. Publications on hospice care for people under 18 years of age were excluded, acknowledging the particular needs of children and young people.
Search results were downloaded into EndNote X9 and duplicates removed. Titles, shortlisted abstracts and full-text articles were independently screened by AR, JT, ST and IW with uncertainty or disagreements resolved by discussion. From the 45,937 records identified, 115 papers met the inclusion criteria. Reference and citation searches of included papers identified a further 13 papers, hand searches yielded a further paper and 1 additional paper was identified from our wider reading. A total of 130 papers were included in the narrative synthesis. Figure 1 presents the PRISMA diagram.

Authors (AR, JT, ST and IW) extracted data independently into a review-specific data extraction form which recorded characteristics of included studies and key findings relevant to the review questions (see online supplemental file 1).

Extracted data were entered into NVivo V.11 for qualitative analysis, with data synthesis using a narrative approach. This was chosen for its applicability to the synthesis of a range of qualitative and quantitative evidence. Three iterative stages were involved: (a) preliminary synthesis of each study from the data extraction forms; (b) study descriptions were grouped together and tabulated based on the review questions addressed and (c) an inductive thematic analysis to identify the main, recurrent and important evidence across the studies in answering the review questions.

Two researchers independently weighted each paper in terms of its strength, quality and contribution towards answering the review questions, using Gough’s ‘Weight of Evidence’ (WoE) criteria with disagreements resolved by discussion (box 2).

**RESULTS**

A summary of the included studies is presented in online supplemental file 2. Gough’s ‘Weight of Evidence’ for the 130 included papers assessed 49 as high, 54 medium and 27 low WoE.

Inequalities in access have been found in relation to diagnosis (reduced for non-malignant disease including heart failure, respiratory disease, renal and liver failure, mental health, learning disability, dementia and neurodegenerative disease (with the exception of motor neuron disease). The oldest old, people from ethnic minority groups, rural and more socioeconomically deprived area are under-represented in hospice services.

**Diagnosis**

Cancer versus non-cancer

A large literature of 29 papers, mostly high/medium WoE, evidence greater hospice referrals and/or deaths for patients with cancer compared with patients without cancer. There is evidence of increasing hospice access for people with non-malignant illness in the UK, Canada and Australia.

Haematological malignancy

Fifteen largely high WoE papers report lower hospice provision for those with haematological malignancies with ORs compared with patients with cancer of around 0.4. Recent years have seen increased deaths in UK hospices among patients with haematological malignancies.
Heart failure

Twelve studies, generally medium/low WoE, evidenced that patients with heart failure are rarely referred to hospice services. Referral rates of patients with heart failure are commonly lower than 5% and patients with heart failure comprise less than 5% of palliative care clinicians’ workload.

Non-cancer respiratory disease

All 11 papers reported low rates of hospice referral, markedly lower than lung cancer, with some indication of increased referrals between 2006 and 2008. Cystic fibrosis patients are under-represented in hospices despite having significant symptom burden.

Renal failure

Access to hospice care for patients with end-stage renal failure (ESRF) has been studied in the UK and Australia with evidence of increasing collaboration between renal units and hospice teams in recent years. Hospice referrals are largely for those receiving conservative management for ESRF rather than people receiving renal replacement therapy.

Liver failure

The five medium/low WoE papers concerning patients with liver failure report them to represent less than 1% of hospice patient caseload with referral often occurring late in the course of the illness.

Neurodegenerative Disease

Papers concerning hospice care for patients with dementia, mostly medium WoE, identify that they are rarely referred for hospice care. Referral is more frequent if there is also a cancer diagnosis, otherwise, it occurs very late in the illness or not at all.

In contrast, patients with motor neuron disease often receive hospice care, with death more common than those with multiple sclerosis or Parkinson’s disease. Patients with multiple sclerosis are more likely to die in hospice if they also have a cancer diagnosis.

Mental health and learning disability

The limited literature of medium/high WoE papers reports patients with schizophrenia rarely access hospice care and people with learning disabilities to be less likely to receive hospice care than the general population.

Age

The extensive and high WoE literature concerning the ‘oldest-old’, people aged 85 years and older, reveals them to be under-represented in hospices across the UK, Australia, New Zealand and Canada. Centenarians seldom die in UK hospices. However, recent evidence suggests that more over 85-year-olds are accessing hospice care in the UK. One low WoE study found age not to affect hospice referral. One study reported the majority of patients accessing a hospice at home service were 78 years of age or older.

Gender and sexuality

The literature concerning gender is inconsistent. Fifteen largely high WoE studies reported that women were more likely to access hospice care than men. However, eight high WoE studies suggested the reverse, and seven high/medium WoE studies reported no differences in access based on gender. No papers were identified concerning LGBTQ+ populations, transgender patients or sexuality of couples.

Marital status

The literature concerning marital status is also inconsistent. While many high and medium WoE studies found married individuals were more likely to access hospice services, other studies (mostly medium WoE) found marital status to be unrelated to hospice access.

Ethnicity and religion

Of the large, mainly high WoE literature concerning ethnicity, the great majority of studies report certain ethnic minority groups to be less likely to receive hospice care than the majority populations in their areas. In contrast, two papers reported some minority groups to be more likely to receive hospice care than their local majority populations.

In the UK, reduced access has been reported for a Pakistani/Indian/Bangladeshi groups and Caribbean/Chinese/African groups. Other studies have reported this not to be the case.

In Australia, indigenous populations are less likely to receive hospice care than their local majority populations. The New Zealand Maori population is similarly less likely to receive hospice care. No research was identified concerning access to hospice care for travellers and prisoners: one study of homeless people reported limited access.

Geography

Many papers evidenced geographical factors to influence receipt of hospice care. Access is greater for those living in urban areas, with closer proximity to a hospice and associated services in Australia, and the UK. Availability of services also varies considerably between regions and countries, which may act as a barrier to General Practitioner (GP) referral.
Systematic review

Socioeconomic status

Many, mostly high WoE studies reveal lower hospice access for people living in areas of lower socioeconomic status (SES). In the UK between 1993 and 2012, the proportion of hospice inpatients from the most deprived quintile reduced, while the proportion from the most affluent quintile increased. However, several high WoE studies have found no association between SES and access. In fact, some studies report greater access among those from lower SES areas.

Other factors

Further factors identified while reviewing the above literature, but neither searched for systematically nor included in the synthesis included: negative public and professional attitudes towards hospice; limited awareness of hospice services; the challenges of difficult conversations surrounding the term ‘hospice’ and the extent or lack of a patient’s social support networks.

DISCUSSION

Summary of findings

This review identifies that the literature evidences that certain groups continue to have unequal access to hospice care; the oldest old, ethnic minorities, people with non-cancer illness, those living in rural areas and areas of social deprivation. The literature concerning gender and marital status is inconsistent. The potential factors influencing the findings of this review, and how they might be addressed are explored below.

Strengths and limitations

This major systematic review has brought together the heterogeneous literature concerning access to hospice care up to late 2019. At times it was unclear how authors from different countries were using the term ‘hospice’; broad inclusion criteria for ‘hospice care’ were employed, including inpatient beds, outpatient, day care, community specialist palliative care and hospice-at-home services while seeking to exclude palliative care wards in hospitals, care homes or other long-term care institutions.

Diagnosis, institutional culture and prognosis

Continuing greater access to hospice care of patients with cancer reflects a persistence of the early focus of the hospice movement on cancer care and the final period of life. The more predictable cancer dying trajectory facilitates easier recognition of the final phase of life, better suiting time-limited hospice care. The greater prognostic uncertainty for people with chronic chest and heart disease, dementia or frailty of old age inhibits timely end of life care discussions and planning and is a continuing barrier to accessing hospice care. Despite their high symptom burden, the prolonged needs of patients without cancer and difficulties in determining when the terminal stage has been entered, leads to late or no hospice referral.

The fact that hospice care in practice continues to primarily address the needs of patients with cancer has been described as an ‘historical anachronism’. A new model of hospice care is urgently needed in which the historical cancer-appropriate ‘one-size-fits-all’ framework is reorganised to prioritise whichever patients need it the most and to better identify those patients with non-cancer illnesses who would benefit from hospice care. The needs of the growing number of people approaching the end of their lives with multimorbidity and frailty presents a major challenge to health and social care services in general and the hospice movement in particular. Innovative collaborative services, based around patient, family and wider community are needed to ensure optimal care for all.

Unique Nneeds

The end-of-life care needs of some groups may be better met by services other than hospice care. The oldest-old, who are under-represented in hospices, may find their long-term care needs, associated with frailty and dementia are better addressed in a care home setting rather than hospice. Many patients approaching the end of life may neither require nor desire specialist palliative care provision from hospice teams, preferring to continue to receive care from their General Practitioner and Community Nursing Team, with whom they have longstanding trusting relationships. Innovative and collaborative models of working are required; in many cases, hospice teams will have more of an educational role rather than direct care provision.

For some groups, therefore, lower use of hospice services may reflect care preferences and choices rather than inequality of provision. Ethnic minority groups also have particular needs at the end of life, including cultural and family expectations and religious practices around dying. Indigenous Australians focus on maintaining spiritual connection to the land and on receiving culturally tailored care from members of the community. However, for LGBTQ+ groups, concerns over social prejudice may affect access to hospice care in addition to particular care needs.

Greater focus is needed on addressing the needs of minority groups; sensitive involvement of these communities in service codesign is required. ‘Home-like’ hospice services are needed for rural and less affluent patients as well as increased sensitivity towards the needs of LGBTQ+ patients and ethnic minority groups. The growing numbers of people reaching the end of their lives in multimorbid frail old-age is a challenge that hospice services need to address urgently.

Other factors

Further factors identified while reviewing the above literature, but neither searched for systematically nor included in the synthesis included: negative public and professional attitudes towards hospice; limited awareness of hospice services; the challenges of difficult conversations surrounding the term ‘hospice’ and the extent or lack of a patient’s social support networks.

DISCUSSION

Summary of findings

This review identifies that the literature evidences that certain groups continue to have unequal access to hospice care; the oldest old, ethnic minorities, people with non-cancer illness, those living in rural areas and areas of social deprivation. The literature concerning gender and marital status is inconsistent. The potential factors influencing the findings of this review, and how they might be addressed are explored below.

Strengths and limitations

This major systematic review has brought together the heterogeneous literature concerning access to hospice care up to late 2019. At times it was unclear how authors from different countries were using the term ‘hospice’; broad inclusion criteria for ‘hospice care’ were employed, including inpatient beds, outpatient, day care, community specialist palliative care and hospice-at-home services while seeking to exclude palliative care wards in hospitals, care homes or other long-term care institutions.

Diagnosis, institutional culture and prognosis

Continuing greater access to hospice care of patients with cancer reflects a persistence of the early focus of the hospice movement on cancer care and the final period of life. The more predictable cancer dying trajectory facilitates easier recognition of the final phase of life, better suiting time-limited hospice care. The greater prognostic uncertainty for people with chronic chest and heart disease, dementia or frailty of old age inhibits timely end of life care discussions and planning and is a continuing barrier to accessing hospice care. Despite their high symptom burden, the prolonged needs of patients without cancer and difficulties in determining when the terminal stage has been entered, leads to late or no hospice referral.

The fact that hospice care in practice continues to primarily address the needs of patients with cancer has been described as an ‘historical anachronism’. A new model of hospice care is urgently needed in which the historical cancer-appropriate ‘one-size-fits-all’ framework is reorganised to prioritise whichever patients need it the most and to better identify those patients with non-cancer illnesses who would benefit from hospice care. The needs of the growing number of people approaching the end of their lives with multimorbidity and frailty presents a major challenge to health and social care services in general and the hospice movement in particular. Innovative collaborative services, based around patient, family and wider community are needed to ensure optimal care for all.

Unique Nneeds

The end-of-life care needs of some groups may be better met by services other than hospice care. The oldest-old, who are under-represented in hospices, may find their long-term care needs, associated with frailty and dementia are better addressed in a care home setting rather than hospice. Many patients approaching the end of life may neither require nor desire specialist palliative care provision from hospice teams, preferring to continue to receive care from their General Practitioner and Community Nursing Team, with whom they have longstanding trusting relationships. Innovative and collaborative models of working are required; in many cases, hospice teams will have more of an educational role rather than direct care provision.

For some groups, therefore, lower use of hospice services may reflect care preferences and choices rather than inequality of provision. Ethnic minority groups also have particular needs at the end of life, including cultural and family expectations and religious practices around dying. Indigenous Australians focus on maintaining spiritual connection to the land and on receiving culturally tailored care from members of the community. However, for LGBTQ+ groups, concerns over social prejudice may affect access to hospice care in addition to particular care needs.

Greater focus is needed on addressing the needs of minority groups; sensitive involvement of these communities in service codesign is required. ‘Home-like’ hospice services are needed for rural and less affluent patients as well as increased sensitivity towards the needs of LGBTQ+ patients and ethnic minority groups. The growing numbers of people reaching the end of their lives in multimorbid frail old-age is a challenge that hospice services need to address urgently.
Public awareness of hospice care
A third factor involves different levels of public awareness of what hospice care provides and for whom. Variation in health literacy and knowledge of health services is present across ethnic minorities and socio-economic groups. The greater access to hospice care by people in more affluent groups may in part reflect their greater health literacy and the presence of articulate relatives who can advocate for hospice services they know to be available.

Similarly, the concentration of hospices in metropolitan areas limits rural patients’ exposure to and knowledge of hospice care. Travelling times further exacerbate impaired access, alongside lack of transport links for relatives.

Hospices need to improve their links with the diverse social and cultural groups in the areas they serve, focusing on enhancing their awareness of available hospice services. Particular focus is needed on reaching out beyond affluent metropolitan areas into deprived and rural populations, supported by telehealth and video consultations.

The inequalities highlighted in this review are not just the responsibility of the hospice movement. System leaders, health and social care managers, policy makers and commissioners need to recognise and understand that while hospices have a vital contribution to palliative and end of life care provision, meeting patient and family needs requires a collaborative and innovative whole-systems approach.

Future research
This review has highlighted a number of areas in which the current literature is absent or very limited, including optimal ways to support ethnic minority groups, homeless people, LGBTQ+ populations, HIV, diabetes and cystic fibrosis.

CONCLUSION
This systematic literature review highlights the persisting unequal access to hospice services for many groups: people with non-malignant disease, the oldest-old, ethnic minorities, living in rural and socio-economically deprived areas, are consistently reported to be referred to or to die in hospice less frequently. A combination of prognostic uncertainty, institutional cultures, unique needs of particular groups and a lack of public awareness of services exacerbate these problems. Equity of access for all is urgently needed, with innovative and collaborative services developed to meet the diverse needs of the whole community.

Equity of access for all remains a challenge for the hospice movement.

</tbody>
</table>

All adults (n = 14,494) who had died of cancer from 1988 to 1994 in Nova Scotia.  
Death  Elderly patients, as well as those with a haematological malignancy, were less likely to be referred to palliative care services.  

49. Vidrine 2016  Place of death in patients with haematological malignancy in North-East of England: Where does this happen and what factors may influence this?  
British Journal of Haematology. 2016; 173 S1: 33  
Case note audit of 39 haematological cancer decedents under the care of a cancer centre in Newcastle-upon-Tyne (UK) between March and August 2015.  
Death  Only two patients (6.5%) with a haematological malignancy died in a hospice.  

114 patients with acute heart failure recruited between January 2013 and August 2013 in Glasgow (UK).  
Death  5% of patients with heart failure died in a hospice.  

Open Heart. 2015; 2(1): e000188.  
Survey of 499 medical professionals working in palliative care in the UK between June and December 2013.  
The average heart failure burden was 3% of the total palliative care workload.  

52. French 2011  Where do elderly patients with heart failure die?  
494 heart failure decedents who had been referred to a heart failure service at Sunderland Royal Hospital (UK) between 2001 and 2007.  
Death  0.9% of the cohort died in a hospice.  

Palliative Medicine. 2006; 20: 603-609.  
Survey of 233 consultants of English SPC services.  
Death  Each service had a mean number of 0.8 patients with heart failure.  

Interview of 20 patients in Doncaster (UK) who had a clinical diagnosis of heart failure between October 2001 and March 2002.  
Death  None of the patients had been referred to SPC services.  

55. Chen 2017  General Practitioner Perceptions of Current Services for Heart Failure Patients: A Qualitative Study.  
Interviews with 20 GPs in Northern Ireland (UK), conducted between June and August 2016.  
Referral  GPs reported poor awareness of the role of SPC services in heart failure.  

British Medical Journal. 1995; 310: 805  
Survey of 10 hospices in North-East London and Essex (UK).  
Referral  Four of the surveyed hospices would consider admitting patients with a primary diagnosis of end stage cardiac failure, only two of these had admitted patients with this condition in the past year. However, this was matched by few requests for palliative care beds for patients with heart failure.  

All patients discharged alive from hospitalization with a primary diagnosis of HF (n=31,274) or ACS (n=54,886) in Alberta Canada between April 2002 and March 2014.  
Death  Less than 2% of patients with HF or ACS died in a hospice, and these rates have not changed over time.  

58. McKinley 2004  Care of people dying with malignant and cardiorespiratory disease in general practice.  
154 decedents with malignant or cardiorespiratory disease from two Leicestershire (UK) general practices between August 2000 and July 2002.  
Death  18% of the cancer decedents died in a hospice compared to 0% of those with cardiorespiratory disease.  

59. Murray 2002  Dying of lung cancer or cardiac failure: a prospective qualitative interview study of patients and their carers in the community.  
Interview and focus groups of 20 patients with inoperable lung cancer and 20 patients with advanced cardiac failure and their main informal and professional carers in Edinburgh (UK).  
Referral  Specialist palliative care and hospice referral was more likely for lung cancer patients than heart failure patients.  

with primary cancers of breast, prostate, head and neck and melanoma had lower odds of dying in hospice. Asian and Aboriginal and Torres Strait Islander people were less likely than Caucasians to receive in-hospice care.

</table>

111. Davison 2001 Where do patients with cancer die in Belfast? Irish Journal of Medical Science. 2001; 170(1): 18-23. Deaths attributable to cancer in Belfast (UK) in 1977 (n = 443), 1987 (n = 455) and 1997 (n = 426). Referral There was an association between place of death and age, marital status, type of cancer and area of residence, but not with social class or gender. Changes over time were reported. HMM = M

112. Dunphy 1990 A comparison of hospice and home care patients: patterns of referral, patient characteristics and predictors of place of death. Palliative Medicine. 1990; 4: 105-111. 404 hospice and 143 home care patients from St Joseph’s Hospice London (UK) who had died during the first six months in 1998. Death Access to hospice was even across genders. HHH = H

114. Gaffin 1996 Opening doors: improving access to hospice and specialist palliative care services by members of the black and minority ethnic communities. British Journal of Cancer. 1996; 29: 551-53. Study of hospice services in two London boroughs (Brent and Newham) and in North Birmingham (UK). Referral Hospices tend to be located in white, middle class areas. People from minority communities were less likely to ask their GP for access to hospice services. LLM = L

115. Karim 2000 Non-white ethnicity and the provision of specialist palliative care services: factors affecting doctor’s referral patterns. Palliative Medicine. 2000; 14: 471-478. Interview of 27 GPs from two wards in Birmingham (UK). Death Language and staff bias were barriers to the referral of black/ethnic minorities to specialist palliative care services. MMH = M

116. Koffman 2004 Dying to be Home? Preferred Location of Death of First-Generation Black Caribbean and Native-Born White Patients in the United Kingdom. Journal of Palliative Medicine. 2004; 7(5): 628-636. 106 black Caribbean patients and 110 white patients from the UK were contacted to produce a sample of 50 cases per ethnic group. These informants were surveyed over a 13 month period. Referral 8% of Caribbean patients died in a hospice, compared to 16% of native-born white patients. This reflected patient preference. HMM = M

118. Worth 2009 Vulnerability and access to care for South Asian Sikh and Muslim patients with life limiting illness in Scotland: prospective longitudinal qualitative study. British Medical Journal. 2009; 338: b183. 92 interviews of patients, family carers and health professionals in Central Scotland (UK). Referral Only two patients accessed specialist palliative care services. Interviews revealed perceived advantages of, and barriers to the receipt of hospice care amongst ethnic minority patients. MMH = M

119. Fountain 1999 Ethnic minorities and palliative care in Derby. Palliative Medicine. 1999; 13: 161-162. 1035 new referrals to Derby (UK) SPC services. Death Ethnic minorities were slightly more likely than white patients to receive certain SPC services. MMM = M

120. Sharpe 2015 Policy for home or hospice as the preferred place of death from cancer: Scottish Health and Ethnicity Linkage Study population cohort shows challenges across all ethnic groups in Scotland. BMJ Supportive and Palliative Care. 2015; 5: 443-451. All cancer patients (n=117,467) aged 25 years or older who participated in the 2001 Scottish census and died from cancer in Scotland between May 2001 and December 2009. Referral The Chinese cohort had the largest proportion of hospice cancer deaths (29.9%). HHM = H

122. Waran 2017 The gap reversed: a review of site of death in the Top End. The Medical Journal of Australia. 2017; 3(207) S1: 39. 308 people, most were men, and most were indigenous Australians. Death Indigenous people died in hospices much less frequently compared to non-indigenous people. LML = L

123. Currow 2012 Referral patterns and proximity to palliative care inpatient services by level. BMC Health Services Research. 2012; 12: 424. Service mapping of 10,064 patients documented in the Palliative Care Death People from the most disadvantaged socio-economic group were less likely to be referred to SPC services. HHM = H

<td>End-of-life care for homeless people: a qualitative analysis exploring the challenges to access and provision of palliative care.</td>
<td>Palliative Medicine. 2018; 32(1): 36-45. 127 participants, made up of: single homeless people (n=28), formerly homeless people (n=10), health- and social-care providers (n=48), hostel staff (n=30) and outreach staff (n=10). Death Accessing hospice services is challenging for homeless people because of stigma, complex multi-morbidities and trauma, substance misuse/dependence, mental health problems, unstable housing conditions, previous experiences that hospices had with supporting homeless people and many more. Even for homeless cancer patients who were not misusing substances, placement within a hospice remained challenging.</td>

<td>Burns 2015</td>
<td>Who provides care for people dying of cancer? A comparison of a rural and metropolitan cohort in a South Australian bereaved population study.</td>
<td>Australian Journal of Rural Health. 2015; 23(1): 24-31. 23,388 survey responses on the death of ‘someone close’. Death In rural areas, half as many people died in hospice compared to those in urban areas. Rates of home death were identical but more rural patients died in hospital compared to urban patients.</td>

<td>Gatrell 2012</td>
<td>Variation in geographic access to specialist inpatient hospices in England and Wales.</td>
<td>Health and Place. 2012; 18(4): 832-840. Death records at 189 specialist adult inpatient hospices in England and Wales, 2003-5. Death There were geographical discrepancies in access to inpatient hospices. Urban areas were well served by hospices but large parts of England and Wales had poor access to hospices. There were many examples of mismatches between supply and demand.</td>

<td>Chukwusa 2019</td>
<td>Urban and rural differences in geographical accessibility to inpatient palliative and end-of-life (PEoLC) facilities and place of death: a national population-based study in England, UK.</td>
<td>International Journal of Health Geographics. 2019; 18(1): 8. 430,467 individual-level death data extracted from Office for National Statistics data. Referral Those who lived more than 10 minutes away from inpatient PEoLC facilities were less likely to die there. The larger the drive time, the less likely they were to die in hospice. The effect of drive time was greater in rural areas.</td>
