Background Nearly half of all deaths occur in hospital. Most of end of life care (EOLC) is delivered by non specialist staff. Training is variable and usually not mandatory. How confident are front line staff in delivering EOLC?

Methods All inpatient setting healthcare professionals (HCPs) at a general hospital (549 beds) were invited (through email, hospital general bulletin, team meetings) to answer a 10 item questionnaire covering the five Priorities for Care of a Dying Person: their confidence rating on a Likert 1–7 scale about essentials of care and communication.

Scores 5, 6 or 7/7 = confident; scores 1–4 = not confident

All responses were anonymised and inputted via Survey monkey.

Results 181 responses were received: 50/181 ward nursing staff, 24/181 junior doctors, 21/181 HCAs, 20/181 consultants. Consultants were most confident; junior doctors and ward staff least. For all the least confident areas were discussing food and fluids and instigating an individualised care plan (Table 1).

Abstract P-68 Table 1 Percent HCPs confident (n=181)

	All% (n=181)	Junior doctors% (n=24)	Ward nurses% (n=50)
Recognise a dying patient	65	67	64
Answer patients questions	51	50	42
Discuss DNACPR	44	58	44
Discuss food, fluids	35	42	34
Answer relatives questions	54	56	44
Individual care planning	40	38	32
Support patient and family	60	46	58
Symptom control	54	54	52

Conclusions

- Hands on ward staff report lowest levels of confidence regarding caring for dying patients and their families.
- The least confident area was around discussing provision of food and fluids, which may explain why the NCDHA 2016 found low levels of discussion regarding fluids (with patients: 18%; with relatives: 39% of cases)
- This questionnaire can identify specific confidence issues and thus be used to plan bespoke teaching sessions.

HOSPICE CARE FOR DEPRIVED AREAS – A REVIEW OF THE EQUITY OF HOSPICE CARE IN OUR AREA

Katie Jerram, P J Morey, Steve Plenderleith. *The Rowans Hospice, Purbrook, UK*

10.1136/bmjspcare-2017-00133.69

Background In response to the 2015 Marie Curie commissioned document 'Equity in the provision of palliative care in the UK: Review of evidence' which found inequalities in the provision of Palliative Care across a number of domains including social deprivation, I undertook a review of our service in the deprived areas within our area of care.

The Rowans Hospice covers Portsmouth city and South East Hampshire and includes coverage of a number of areas which are within the 20% most deprived in the country.

Method I identified all patients referred to the inpatient unit or our Hospice at home service from deprived areas over one year, using Office of National Statistics data, Indices of Multiple Deprivation and computerised records. I noted demographics, diagnosis, referrer, time with service, preferred and actual place of death.

Results Compared with the area as a whole, I found that for patients from deprived areas:

- Access to Hospice at Home and inpatient services appears equitable
- Proportion of cancer to non-cancer seems similar
- Average time under the care of Hospice at Home is lower
- Likelihood of being admitted to the Hospice more than once is lower
- Length of inpatient stay is longer
- Chance of a greater than 21 day stay is longer
- PPD is less likely to be recorded
- Dying at home was less likely: but if patients had expressed a wish to die at home they were more likely to achieve this
- More likely than the national average to achieve their PPD

Conclusions The findings of this service review were interesting and broadly positive. Exploring some of the differences found with both service users and professionals would be helpful, and a new initiative (The Living Well Centre) may allow us to connect with those who may not engage with the traditional Hospice model.

Introduction Cervical lymphadenopathy is a sign that can be presented in many diseases condition. We are presenting a case of fever with cervical lymphadenopathy due to kikuchi Fujimoto diseases. Kikuchi lymphadenitis is a rare, benign condition of unknown cause usually characterised by cervical lymphadenopathy and fever. While, 40% of patient with kikuchi disease were initially misdiagnosed as having lymphoma and were consequently over treated with chemotherapy. This pitfall remains an active source of diagnostic error.

Case Mr. Am is a 25 years old Malay man initially admitted under Internal Medicine department with history of fever and neck swelling for more than 2 weeks. During admission, his routine blood tests were normal. Chest X ray was also clear. Thereafter patient transferred under Palliative medicine unit for the further evaluation and management. His CT-TAP (thorax, abdomen and pelvis) reported as normal study. He underwent FNAC (fine needle aspiration and cytology) of the cervical lymph node which showed T cell lymphoma. Although, FNAC report did not clinically correlate. Therefore, for the further workup we performed bone marrow aspiration and trephine. His bone marrow showed leukopenia. We started to treat with steroid which showed some clinical improvement. Mr. Am was seen in the NUH (National University hospital) Singapore for second opinion. His working
