Methodology Using Shropshire Doctors Co-operative Ltd (Shropdoc’s) recorded data we have collated a representative picture of the palliative care practice over a year period from 161 OOHGP patient interactions.

Results 31% of home visits (HV) had documentation of potential reversible factors and out of those 72% were with the patient’s estimated prognosis greater than 48 hours. Infection being the most common (57%) reversible factor, the majority being a lower respiratory tract infection. Overall 5.7% of OOH GP palliative HV’s resulted in hospital admission, however this decreased to 0.6% adjusting for an estimate of the patient’s prognosis to be less than 48 hours. 16% were admitted if the patient had a potentially reversible co-existing condition. 33% of consultations had documentation regarding a continuous subcutaneous infusion (CSCI), 86% of CSCI interventions were made with a prognosis of less than 48 hours. There were CSCI infusion issues requiring an OOHGP 3.4% of the time. Overall anticipatory medications were prescribed 39% of the time.

Conclusion The OOHGP deals with a wide variety of scenarios for a heterogeneous population. The symptoms and treatments instigated are on the most part expected within emergency palliative care. This data begins to quantify and describe the role being performed by OOHGP and has implications for service provision and potentially the necessity of 24 hour specialist palliative provision.

113 THE SWINBURNE SLOT: A CLINIC-BASED SERVICE FOR DETERIORATING PATIENTS WITH INTERSTITIAL LUNG DISEASE

1Emily Kavanagh, 1Eve Palmer, 1Julie Harper, 2Claire Donaldson, 3A John Simpson, 1Ian Forrest, 2Anne-Marie Boullie, 1Marie Curie Hospice Newcastle; 1Newcastle Hospitals NHS Foundation Trust; 2Newcastle University

Introduction and objectives Patients with interstitial lung disease (ILD) can deteriorate quickly. It can be difficult to determine whether this is due to disease progression or other potentially reversible processes. Such patients are often known to multiple services; carer feedback in 2016 highlighted it is difficult to know who to approach. In response, the Newcastle ILD team introduced a weekly 30 min rapid access clinic slot (Swinburne Slot, SS) with the aim of determining reversibility and to support patients in their preferred place of care. Our objective was to evaluate this service, which may have practice implications for other teams.

Methods We collected data on how the SS was utilised between 12/09/2016 and 21/03/2017. This included appointment outcome; for example, further imaging or referral to specialist palliative care. Additionally, we collected data on acute hospital admissions within 30 days. Data were obtained using electronic medical records and telephone calls to General Practitioners.

Results The SS was utilised 24 times during the 28 week evaluation period. The most frequent clinic outcomes were adjustment to patient management and improved access to palliative care. We present the SS as a workable model which could be replicated by other multidisciplinary teams.
accepted it (74.6% of those offered). 238 patients accepted a research pack, with 105 returning questionnaire 1 (44.1% response rate), and 26 returning questionnaire 2 (24.8% of initial respondents). Questionnaire 1 (patients) – 40% found it difficult or burdensome repeating information to HCPs, and almost 70% were interested in a PHR to reduce repeating information. Questionnaire 2 (patients) – 74% found it the passport easy to use, but only a few actually used it regularly. Some felt the passport helped conversations with family and HCPs about day-to-day and future care. Over 60% stated the PHR was ‘very’ or ‘quite’ useful, and would recommend it to others. Questionnaire and focus group with HCPs indicated it was mainly patients and relatives who used the passport, not non-palliative HCPs. Half felt the passport was initially well received, but only 4 (22%) felt it was used regularly by patients or their families. More found it useful to talk about facilitation discussion about future care compared with day-to-day care.

Conclusions While initial uptake of the passport was high, use appeared low. This evaluation does not support widespread use of a PHR in palliative care, but it may be helpful to individuals, especially earlier in their disease trajectory.

In the second initiative, run charts demonstrated statistically significant improvements in the rate of assessment, reassessment and evaluation of terminal agitation (p<0.05). Routine review and dissemination of data with the frontline teams in these initiatives enhanced collaborative engagement, motivation and success.

Conclusion SPC and run charts can be used to measure the impact of interventions, and contribute to improvements in EOLC.

#### 117 UNMET NEEDS FROM MENTAL AND PHYSICAL HEALTH CO-MORBIDITIES: A PROSPECTIVE AUDIT IN COMMUNITY PALLIATIVE CARE

Sarah Yardley, Monika Gorny. Central and North West London NHS Foundation Trust
10.1136/bmjspcare-2018-ASPabstracts.144

**Background** Increasingly patients referred to community specialist palliative care (SPC) have multiple co-morbidities including psychiatric and mental health needs in addition to physical disease. Access to psychiatric services is variable. There is no national standard for community-based shared care in this context and both palliative and psychiatric professionals report challenges.

**Methods** This prospective audit aimed to:

- establish local need for community psychiatric liaison/shared working;
- identify unmet needs for quality improvement. Patients discussed in a SPC community multidisciplinary team meeting were screened for three months.

**Inclusion criteria:**

- SPC staff had concerns about managing mental health needs; contact with psychiatric services within last year; current medication prescription for psychiatric disorder. Exclusion criteria: not meeting inclusion criteria and dementia if SPC considered this appropriately managed without psychiatric input.

**Results** In 182 case discussions (May–July 2017), 35 patients (new n=19/96, complex n=16/86) with unmet mental health needs were identified. 26 had a formal psychiatric diagnosis; 12 had on-going psychiatric care. 20 had never had contact with local community mental health team, 3 were previously discharged. SPC attempted shared care with mental health services in 10 cases (3 via GP, 1 patient refused, 1 via oncology psychology services, 4 received psychiatry services and 1 was accepted but died before being seen). Four patients’ needs were first identified by psychiatric liaison teams during hospital admissions. SPC records demonstrate a further 17 patients whose current needs exceeded SPC expertise but no shared care or referrals were attempted. The remaining 4 patients’ needs were met directly by SPC. Exemplar vignettes with further learning will be shared.

**Conclusions** This demonstrates significant unmet mental health needs in our community SPC population. Addressing needs requires proactive liaison between SPC and mental health services with identification of best practice models that also integrate specialist services with general practice.
