114 PALLIATIVE CARE AND THE ACUTE STROKE WARD: NEW BEGINNINGS?
Jeena Ackroyd, Anand Nair. Calderdale and Huddersfield NHS Foundation Trust

10.1136/bmjspcare-2018-ASPabstracts.141

Methodology Using Shropshire Doctors Co-operative Ltd (ShropDoc’s) recorded data we have collated a representative picture of the palliative care practice over a year period from 161 OOHGP patient interactions.

Results 31% of home visits (HV) had documentation of potential reversible factors and out of those 72% were with the patient’s estimated prognosis greater than 48 hours. Infection being the most common (57%) reversible factor, the majority being a lower respiratory tract infection. Overall 5.7% of OOH GP palliative HV’s resulted in hospital admission, however this decreased to 0.6% adjusting for an estimate of the patient’s prognosis to be less than 48 hours. 16% were admitted if the patient had a potentially reversible co-existing condition. 33% of consultations had documentation regarding a continuous subcutaneous infusion (CSCI), 86% of CSCI interventions were made with a prognosis of less than 48 hours. There were CSCI infusion issues requiring an OOHGP 3.4% of the time. Overall anticipatory medications were prescribed 39% of the time.

Conclusion The OOHGP deals with a wide variety of scenarios for a heterogeneous population. The symptoms and treatments instigated are on the most part expected within emergency palliative care. This data begins to quantify and describe the role being performed by OOHGP and has implications for service provision and potentially the necessity of 24 hour specialist palliative provision.

115 EVALUATION OF THE USE OF A PATIENT HELD RECORD IN SPECIALIST PALLIATIVE CARE
Clare White, Jenny Sproule, Paula Brogan, Max Watson. Northern Ireland Hospice, University Ulster

10.1136/bmjspcare-2018-ASPabstracts.142

Introduction The Royal College of GPs in Northern Ireland created a Patient Held Record (PHR) for patients with progressive, life-limiting illness and their families. This study evaluates its usefulness in the specialist palliative care context.

Methods A prospective longitudinal cohort study through a hospice community service. Patients were given questionnaires with the passport and after 4–6 weeks. Hospice Healthcare Professionals (HCPs) completed a questionnaire and focus group after 8 months.

Results From September 2016–June 2017, 550 patients were screened, 347 (63.1%) were offered a passport and 259

116 MEASURING THE IMPACT OF END OF LIFE CARE QUALITY IMPROVEMENT (QI) PROJECTS
10.1136/bmjspcare-2018-ASPabstracts.143

Aim To demonstrate the application of QI methodology to improving end of life care (EOLC), using improvement data (run charts/statistical process control charts (SPC)) to measure the impact of interventions.

Background QI methods are applied widely across healthcare. SPC and run charts are employed to demonstrate if interventions can lead to sustained and significant improvements. Identifying variables that suit themselves to measurement by repeated data points is more of a challenge for interpersonal aspects of care (such as palliative and EOLC) than for technical interventions (Conry M, 2012).

Methods QI methodology and measures were employed in two QI EOLC initiatives in a large acute NHS trust. The first was a multidisciplinary collaborative to improve the care of patients at risk of clinical deterioration, to reduce avoidable deterioration and/or inappropriate cardiopulmonary resuscitation. The second was an intervention led by the Palliative Care Team to improve the assessment and management of terminal agitation on designated wards. SPC and run charts were created for these initiatives, with baseline data pre-intervention and on-going data collection during the testing, implementation and sustainability phases.

Both initiatives were developed following identification of local need; were led by frontline teams and empowered ward level innovation.

Results In the first initiative SPC charts demonstrated sustained, significant 25% reductions in cardiac arrest calls across the trust, and on 14 pilot wards a 125% increase in patients with a treatment escalation plan and 75% increase in documented CPR decisions.

In the second initiative, run charts demonstrated statistically significant improvements in the rate of assessment, reassessment and evaluation of terminal agitation (p<0.05). Routine review and dissemination of data with the frontline teams in these initiatives enhanced collaborative engagement, motivation and success.

Conclusion SPC and run charts can be used to measure the impact of interventions, and contribute to improvements in EOLC.

117 UNMET NEEDS FROM MENTAL AND PHYSICAL HEALTH CO-MORBIDITIES: A PROSPECTIVE AUDIT IN COMMUNITY PALLIATIVE CARE
Sarah Yardley, Monika Gamy. Central and North West London NHS Foundation Trust
10.1136/bmjspcare-2018-ASPabstracts.144

Background Increasingly patients referred to community specialist palliative care (SPC) have multiple co-morbidities including psychiatric and mental health needs in addition to physical disease. Access to psychiatric services is variable. There is no national standard for community-based shared care in this context and both palliative and psychiatric professionals report challenges.

Methods This prospective audit aimed to:

- establish local need for community psychiatric liaison/shared working;
- identify unmet needs for quality improvement. Patients discussed in a SPC community multidisciplinary team meeting were screened for three months.

Inclusion criteria:

- SPC staff had concerns about managing mental health needs; contact with psychiatric services within last year; current medication prescription for psychiatric disorder. Exclusion criteria: not meeting inclusion criteria and dementia if SPC considered this appropriately managed without psychiatric input.

Results In 182 case discussions (May–July 2017), 35 patients (new n=19/96, complex n=16/86) with unmet mental health needs were identified. 26 had a formal psychiatric diagnosis; 12 had on-going psychiatric care; 20 had never had contact with a local community mental health team, 3 were previously discharged. SPC attempted shared care with mental health services in 10 cases (3 via GP, 1 patient refused, 1 via oncology psychology services, 4 received psychiatry services and 1 was accepted but died before being seen). Four patients’ needs were first identified by psychiatric liaison teams during hospital admissions. SPC records demonstrate a further 17 patients whose current needs exceeded SPC expertise but no shared care or referrals were attempted. The remaining 4 patients’ needs were met directly by SPC. Exemplar vignettes with further learning will be shared.

Conclusions This demonstrates significant unmet mental health needs in our community SPC population. Addressing needs requires proactive liaison between SPC and mental health services with identification of best practice models that also integrate specialist services with general practice.
