ABSTRACT

Background Decision-making in palliative care usually involves both patients and family caregivers. However, how concordance and discordance in decision-making manifest and function between patients and family caregivers in palliative care is not well understood.

Objectives To identify key factors and/or processes which underpin concordance and/or discordance between patients and family caregivers with respect to their preferences for and decisions about palliative care; and ascertain how patients and family caregivers manage discordance in decision-making in palliative care.

Methods A systematic review and narrative synthesis of original studies published in full between January 2000 and June 2021 was conducted using the following databases: Embase; Medline; CINAHL; AMED; Web of Science; PsycINFO; PsycARTICLES; and Social Sciences Full Text.

Results After full-text review, 39 studies were included in the synthesis. Studies focused primarily on end-of-life care and on patient and family caregiver preferences for patient care. We found that discordance between patients and family caregivers in palliative care can manifest in relational conflict and can result from a lack of awareness of and communication about each other's preferences for care. Patients' advancing illness and impending death foster consensus between patients and family caregivers.

Conclusions Patients and family caregivers in palliative care can accommodate each other's preferences for care. Further research is needed to fully understand how patients and family caregivers move towards consensus in the context of advancing illness.

INTRODUCTION

Family caregivers have significant caregiving roles in palliative care, providing important support to the person they care for. Family caregivers provide a combination of physical, psychological, emotional, social and financial support to the person with a life-limiting illness. Care is an inherently relational activity which widens the focus of palliative care
to family. Assuming caregiving responsibilities for a significant other with palliative care needs often means that family caregivers are, by choice or circumstance, involved in decision-making in palliative care.

Decision-making among patients and family caregivers in palliative care is complex. Patient and family caregiver preferences for care are shaped by one another because how patients and family caregivers navigate the illness journey is rarely independent of each other. Patients face difficult decisions about multiple domains of care (e.g., symptom management, advance care planning and end-of-life care), and engage with a range of healthcare professionals who deliver formal care. In some cases, healthcare professionals situate the patient’s perspective central to care plans, but patients also become dependent on their family caregivers. Family caregivers in palliative care provide the majority of caregiving which their relative or friend receives and often function as key advocates and care coordinators. Family caregivers in palliative care make decisions with patients or sometimes for patients in situations where decision-making has been delegated. Indeed, family caregiver perceived burden can be a function of increasing family caregiver responsibility for decision-making. Family caregivers in palliative care themselves also have care needs that are addressed by formal services, including, for example, psychosocial support and respite services, but there has been less focus on how patients impact on the decision-making process pertaining to formal care and support accessed by family caregivers. Lastly, while the palliative care approach recognises the needs of both patients and family caregivers, not all patients seek to involve significant others when making decisions about care, even when a significant other is available.

We know that patients and family caregivers in palliative care can have similar and different preferences for care, and that patient and family caregiver preferences and needs can diverge with illness progression. Moreover, patients and family caregivers can have different perceptions of treatment decision-making processes. However, prior to this review, it was unclear how concordance or discordance manifests and functions between patients and family caregivers in palliative care, with respect to their preferences for care and the decisions they make about care. Moreover, little was known about how patients and family caregivers manage their discordance when making decisions about care. Hence, the aims of this systematic review were to, first, identify key factors and/or processes which underpin concordance and/or discordance between patients and family caregivers in decision-making in palliative care and, second, determine how patients and family caregivers manage their discordance in decision-making in palliative care.

**METHODS**

We conducted a systematic review with narrative synthesis of original evidence on concordance and discordance between patients and family caregivers in palliative care, pertaining to their preferences for care and decision-making in care. The review was conducted between June and September 2021 and the full search was run in June 2021. We carried out the search in line with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) to detail the number of records found, included and excluded and the reasons for exclusion.

**Search strategy**

The search was conducted using the following databases: Embase; Medline; CINAHL; AMED; Web of Science; PsycINFO; PsycARTICLES; and Social Sciences Full Text. A Boolean search strategy was first devised by authors SMS and DM in Embase and reviewed and approved by GF. The search terms were agreed through multiple rounds of discussion between SMS, DM and GF, to ensure that all terms were relevant and comprehensive. The search strategy was then tailored to the other databases searched. All search terms and the full search strategy are detailed in the online supplemental appendix 1.

**Inclusion/exclusion criteria**

We included original peer-reviewed research, published in full and in English between January 2000 and June 2021. We limited our search to this period because more historical data may not be as relevant to current practice in the context of social change over time. We took the definition of palliative care as active holistic care of individuals with serious health-related suffering due to severe illness. Only studies in which data had been captured from the patient and family caregiver were included. This was because the focus of the review lay in the context of the relationship between patients and family caregivers. Studies were included if they reported on dimensions of (or any factors associated with) concordance and discordance between patients and their family caregivers, which pertained to their preferences for care and/or decision-making in care. The term ‘family’ in palliative care includes formalised or familial-based relationships, and those that are patient defined or self defined as significant. Our definition of family caregiver extended beyond familial-based relationships, and we included studies where family caregivers were family members, friends or any other form of significant other once they had been recruited as participants who had provided and/or were providing informal care and/or support to the patient. The review was limited to studies where patient participants were ≥18 years.

We did not limit the review to specialist palliative care or to end-of-life care, but we did exclude studies where patient participants did not have clearly
advancing and non-curable conditions. In addition, although our inclusion was aimed at original peer-reviewed studies, we excluded intervention-based studies including randomised controlled trials as their focus was on acceptability or effectiveness of a given intervention rather than on explaining concordance or discordance in decision-making. We also excluded single-case studies. Studies which reported only on the patient or only on the family caregiver were excluded.

Extraction
The full search found 4782 records in total. The full set of records was uploaded to Covidence and 2011 duplicates were removed. SMS and GF screened all remaining records by title and abstract following the inclusion/exclusion criteria. A total of 2601 records were deemed not relevant. The remaining 170 records were then sought for full retrieval by SMS and assessed for eligibility. Any uncertainty regarding inclusion or exclusion of studies from this point was resolved by a collective review of the full text by SMS and GF. Figure 1 outlines the PRISMA flow diagram of the conducted review and the number of studies that met the criteria for inclusion.

Quality assessment
We used the Standard Quality Assessment Criteria for Evaluating Primary Research Papers and the Mixed Methods Appraisal Tool (MMAT) to assess the quality of the included studies. Twenty-one quantitative, 15 qualitative, and 3 mixed-methods studies were included in the review. The Standard Quality Assessment Criteria for Evaluating Primary Research Papers was used to appraise the quantitative and qualitative studies because it allows for a replicable method of assessing the quality of a quantitative or qualitative study. Quality rating or summary scores range from 0 to 1.0 for each study. SMS appraised these studies, and GF independently scored a subset for internal consistency. The summary scores across the studies ranged from good to strong scores, with no study scoring below 0.7. The quality of the mixed-methods studies was assessed using the MMAT, chosen because it includes the option for assessing the quality of a mixed-methods study and accounts for the characteristics specific to each component (ie, qualitative, quantitative and mixed methods) of a mixed-methods study. The mixed-methods studies were appraised to be of moderate to high quality. We tabulated all of the 39 included studies into a table (see online supplemental table 1) under the standard domains of authors, location/setting, participants, aims, methods and key findings. Tables 1–3 outline the quality assessment of the included studies.

Synthesis
We conducted a narrative synthesis of the selected studies. A narrative synthesis is commonly used to synthesise studies in a review when studies are heterogeneous in design. First, we looked at all evidence in each study which reported on concordance and/or discordance between patients and family caregivers with respect to the focus of the review. We then undertook a preliminary synthesis of the studies. This comprised an exhaustive search in each study for factors and/or processes which related to or helped explain concordance and/or discordance between patients and family caregivers in terms of their preferences for care and/or decision-making in care. Here, we undertook a short textual description for each study and tabulated the findings from each study.

We then explored relationships in the data by comparing the above findings between and across studies. We looked for both similarities and differences in the findings and documented these frequently by engaging in qualitative descriptions of the data. We proceeded with expansion of the synthesis via clustering or grouping the findings into categories that best accounted for relationships between the findings and helped answer the aims of the review. The grouping of findings into categories was done collectively by SMS and GF, and the naming of categories was agreed between SMS and GF. The robustness in the synthesis was underpinned by the quality of the studies included in the review and by each study having clearly met the criteria for inclusion.

**RESULTS**

**Summary of studies**

Studies were conducted in Australia, the USA, Canada, Denmark, UK, Ireland, South Korea, Taiwan, Singapore, Germany, Hong Kong and the Netherlands. Quantitative studies reported more on factors associated with concordance and/or discordance while qualitative studies reported on reasons for and/or processes underpinning concordance and discordance. None of the studies aimed from the outset to investigate how patients and family caregivers manage discordance in decision-making.

The studies investigated a range of palliative and end-of-life care domains and contexts, including place of death, advance care planning and advance directives, artificial nutrition and hydration, cardiopulmonary resuscitation, hospice care, end-of-life care in general (including life-sustaining treatment, life-extending treatment and treatment approaching death), and, more broadly, care over the disease trajectory.

Other studies focused more specifically on patients and family caregivers’ preferences, values and judgements with respect to care, and on the family caregiver and the broader family role in the decision-making process.

Although many studies examined concordance in care preferences and decision-making between patients and family caregivers, only nine studies explicitly focused on discordance, disagreement and/or conflict between patients and family caregivers.

Just over half of the studies included had a cancer-only patient population, while other studies included patient populations for specific diseases including end-stage kidney disease and amyotrophic lateral sclerosis, or a patient population comprising different progressive neurological diseases. The remaining studies recruited patient populations across a spectrum of advanced illness and disease. Care settings included specialist cancer centres, inpatient and outpatient hospital care, specialist palliative care (including hospice care), a nursing home and home care. In a minority of studies, patient participants were recruited through hospice or other dedicated and/or specialist palliative care settings. Family caregivers were primarily spouses or partners, but also included parents, adult children, siblings and friends. Overall, family caregiver participants comprised a combination of significant others and varied both within and across studies. The sample in some studies was limited to patient–caregiver dyads only.

**Aligned and misaligned preferences and priorities**

Several studies investigated patient and family caregiver preferences for care which were focused primarily on...

Rating mixed-methods studies using MMAT involves scoring criteria 1.1–1.5 (qualitative dimension) plus criteria 2.1–2.5 (quantitative—RCTs) or criteria 3.1–3.5 (quantitative—non-randomised trials) or criteria 4.1–4.5 (quantitative descriptive) plus criteria 5.1–5.5 (mixed methods).

Criteria 2.1–2.5 or criteria 3.1–3.5 of the MMAT are not listed here because none of these studies are intervention studies. RCT, randomised controlled trial.
patient care, and for the most part, patient end-of-life care.\textsuperscript{21–25} 28 29 34–36 38–41 46–48 53–55 57 Both patients and family caregivers prioritised pain and symptom management.\textsuperscript{23} 24 35 57 However, patients and family caregivers differed with respect to other preferences for care. For example, patients had a strong preference for information to be provided,\textsuperscript{37} while family caregivers wanted more information about end-of-life care than patients.\textsuperscript{27} Family caregivers also wished for more healthcare professional engagement and support (including bereavement support) than did patients.\textsuperscript{37} 55 However, patients’ preferences to avoid family caregiver burden and have their personal affairs in order before death could be underestimated by family caregivers.\textsuperscript{23} 24 57

Life-prolonging care versus conservative care was an area of potential conflict between patients and family caregivers. Family caregivers tended to favour more active and life-sustaining treatment options than did patients.\textsuperscript{29} 31 52 56 57 59 Some patients preferred a lesser role in decision-making,\textsuperscript{23} and trusted their family caregivers to make decisions about their care.\textsuperscript{42} 47 However, family caregiver judgements about patient preferences were in some cases incorrect\textsuperscript{23} 32 33 and related more to family caregiver preferences for care than to the patient’s preferences for care.\textsuperscript{32} Agreement between patients and family caregivers manifested when patients and family caregivers had knowledge of the disease\textsuperscript{39} and of treatment and end-of-life care options available to the patient,\textsuperscript{30} 57 and when family caregivers were aware of patients’ preferences for end-of-life care.\textsuperscript{23} 24 43 48 Conversely, discordance was associated with poor communication between patients and family caregivers\textsuperscript{34} and manifested when patients and family caregivers had insufficient knowledge of the disease and treatment options.\textsuperscript{28}

The familial context to concordance and discordance

Conflict between patients and family caregivers and within the wider family could limit reaching agreement in decision-making about care.\textsuperscript{40} 44 45 47 51 56 Family conflict was in some cases more stressful for patients than the experience of receiving formal care and treatment.\textsuperscript{51} Nonetheless, patients who preferred a more independent decision-making style were more likely to have their families report that decisions were made in the style that the patient preferred.\textsuperscript{58} Family caregivers’ family roles shaped concordance and/or discordance between patients and family caregivers.\textsuperscript{34} 36 59 Concordance was higher if family caregivers were spouses,\textsuperscript{36} and spouse caregivers tended to leave final decisions up to the patient.\textsuperscript{39} Adult children caregivers, however, preferred a more shared decision-making style and sought more information than spouse caregivers.\textsuperscript{59} Of note, being an adult child caregiver was associated with concordance with patients for end-of-life care and being a parent caregiver was associated with concordance with patients for disclosure of terminal illness.\textsuperscript{34}

Caregiver commitment versus caregiver burden

Tension between family caregiver commitment to the patient and perceived burden of family caregiving featured in a number of studies.\textsuperscript{42} 46 49 50 54 Dependency on their family caregivers troubled some patients because patients wished not to be a burden on their family caregivers.\textsuperscript{42} 46 49 50 54 57 38 However, family caregivers were committed to providing care to alleviate distress for patients despite the burden of care.\textsuperscript{46} 49 50 54 and even desired to limit information to patients to reduce psychological burden for patients.\textsuperscript{42} Some patients and family caregivers distanced themselves from each other in decision-making to maintain a sense of normality and avoid conflict,\textsuperscript{46} but such action could limit patient and family caregivers in sharing their concerns with each other.\textsuperscript{46} 50 Indeed, a lack of family caregiver involvement in care could lead to negative experiences for the family caregiver surrounding patient death.\textsuperscript{53} In many cases, family caregivers wanted to be actively involved in decision-making\textsuperscript{26} 27 47 49 50 54 and supported patients by advocating on their behalf\textsuperscript{47} and respecting patient autonomy.\textsuperscript{35} 49

Planning end-of-life care and place of death

Discussion surrounding end-of-life care was challenging for both patients and family caregivers.\textsuperscript{43} 45 47 48 56 However, planning ahead for end-of-life care was a useful coping strategy for patients and family caregivers.\textsuperscript{46} 50 Denial of or not engaging in conversation about the impending death acted as a barrier to making decisions about care including end-of-life care.\textsuperscript{47} 51 52 Preference with respect to place of death featured across studies.\textsuperscript{23} 24 35 36 40 46 48 54 Patients and family caregivers were generally consistent on place of death, apart from one study which reported that half of patient–family caregiver dyads disagreed on place of death.\textsuperscript{35} Higher agreement on place of death was associated with the family caregiver being a spouse,\textsuperscript{36} the patient having high levels of functional dependency,\textsuperscript{36} patients and family caregivers having had discussed preferences\textsuperscript{24} and patients’ own assessment of family caregivers’ knowledge of patient preferences.\textsuperscript{24} Patient and family caregiver concordance was also more likely if patients and family caregivers agreed on other aspects of end-of-life care.\textsuperscript{36} Discordance on place of death was more common in situations where family caregiver burden was high\textsuperscript{23} 16 46 and where patients were aware of their prognosis.\textsuperscript{36} Family caregivers’ lack of knowledge of patient preference for place of death could lead to uncertainty surrounding final decisions\textsuperscript{58} and some family caregivers regretted when death at home was not possible.\textsuperscript{54}

Managing discordance

No study aimed from the outset to investigate how patients and family caregivers manage discordance in decision-making in care, but some studies did report...
ways in which patients attempted to manage discordance. In one study, patients chose to forego their own preferences for care in favour of their family caregivers’ preferences for care. In another study, patients did not consider advance care planning to address potential decisional conflict with family caregivers. However, progression of the patient’s illness meant that patients and family caregivers became attuned to the benefit of reaching consensus with respect to end-of-life care decisions. Indeed, negotiation featured when patients and family caregivers jointly decided to move to conservative care or hospice care.

Family caregiver lack of knowledge of patient preferences could foster uncertainty surrounding decisions. However, advance care planning and advance directives opened dialogue between patients and family caregivers and in turn facilitated consensus among patients and family caregivers. Although prior communication did not necessarily improve family caregivers’ substituted judgement on patients’ own preferences for care, advance care planning enabled family caregivers to follow patient wishes even if family caregivers differed in their preferences for care. Discussing death and end-of-life care was difficult and could instigate conflict in the family, particularly when there were pre-existing tensions. However, having healthcare professionals to initiate end-of-life conversations assisted patients and family caregivers in the decision-making process.

**DISCUSSION**

The focus of this review was to identify key factors and/or processes which underpin or help explain concordance and/or discordance between patients and family caregivers in palliative care with respect to their preferences for care and the decisions they make about care, and to ascertain how they manage their discordance in decision-making pertaining to care. In this review, we found that concordance and/or discordance between patients and family caregivers is shaped by multiple factors, including patient and family caregiver perceptions of caregiver burden, patient resistance to burdening family caregivers, family roles and relations, family awareness of patient preference, quality of communication between the patient and family caregiver, patient and family caregiver knowledge of disease and treatment options, patient and family caregiver coping strategies in the context of advanced illness, patient and family caregiver judgements about life-prolonging treatment versus end-of-life care, and by how accepting or not the patient and family caregiver feel towards end-of-life care and the impending death. While discordance between patients and family caregivers is often associated with relational conflict,

open discussion and dialogue about patient future care can help move patients and family caregivers towards consensus. All studies were conducted in economically developed countries and so the findings of the review are rooted in this context.

Some key findings in our review resonate with non-palliative care literature on how concordance and discordance manifest between patients and family caregivers in decision-making about care. For example, patients with generic healthcare needs and their family caregivers also feel conflicted about caregiver burden.

People with non-life-limiting illness and their family caregivers also make decisions in the context of knowledge about disease and treatment options, and the strain and demands of living with debilitating illness.

Open communication between patients with non-life-limiting illness and family caregivers can also promote consensus in decision-making. In the context of palliative care, the findings of our review resonate with literature on patient and family caregiver decisional conflict. Patients and family caregivers in palliative care have capacity to move from periods of decisional conflict to a mutual understanding, in the context of advancing illness and the impending death. Moreover, patients and family caregivers can accommodate changes in one another’s decision-making roles in end-of-life care.

**Clinical implications**

The findings of our review have implications for clinical care and practice. First, the evidence confirms that patients and family caregivers in palliative care have both similar and different preferences for care. However, of key importance is the fact that patients and family caregivers may not necessarily be attuned to one another’s preferences. Attention to patient and family caregiver knowledge of one another’s preferences and to strategies to increase patient and family caregiver mutual understanding could help optimise the decision-making process for both patients and family caregivers. Family caregivers in some cases may favour life-prolonging interventions more than patients, but increased knowledge about patient disease and treatment options can aid discussion about end-of-life care.

Second, the evidence signals that patients and family caregivers in palliative care do have capacity to approximate to one another’s preferences for care, particularly when patients approach end-of-life care, and even when both patients and family caregivers are conflicted about the burden of care. In addition to the provision of formal support to the family caregiver, open discussion between patients, family caregivers and healthcare professionals about concerns in relation to caregiver burden could prove highly beneficial for both patients and family caregivers.

Third, the review highlights the wider impact of family on patients’ and family caregivers’ approach to decision-making in palliative care and how the familial
relationship between the patient and family caregiver shapes preferences for both patients and family caregivers. Healthcare professionals should consider the impact of the wider family on concordance and/or discordance between patients and family caregivers and the expectations of both patients and family caregivers in the context of their family roles.

**Recommendations for research**

We identified that patient illness progression and patient and family caregiver recognition of end-of-life care and impending death were key contexts that fostered consensus between patients and family caregivers. Moreover, engaging in dialogue about future care was a key factor that facilitated patients and family caregivers to accommodate to differences in their preferences for care. Systematic reviews have already focused on the effects of advance care planning for people with life-limiting illness. Research focused on how best to facilitate consensus between patients and family caregivers through advance care planning could prove effective for both patients and family caregivers.

As stated, we did not include intervention-based studies in our review because the focus was on factors related to and/or processes underpinning concordance and/or discordance between patients and family caregivers as opposed to how effective or acceptable interventions were to patients and family caregivers or whether patients and family caregivers differed or not on acceptability of interventions. However, from the evidence reviewed, developing interventions which focus on helping patients and family caregivers understand and accommodate each other’s preferences for care could prove beneficial in alleviating concerns for both patients and family caregivers.

Only in a minority of the studies synthesised were patient participants recruited directly from designated or specialist palliative care facilities, even though this review was limited in its focus to care preferences and decision-making among patients with clearly advancing illness and their family caregivers. Patient recruitment for research can be challenging in palliative care. Health status of patients can alter suddenly, and the severity of patient illness can in some cases limit patient participation. Nevertheless, more studies that recruit patients and family caregivers from designated or specialist palliative services including hospice care could help pinpoint more clearly how and why patients and family caregivers approximate to each other’s preferences in the context of advancing illness.

Lastly, we found few studies which reported on patient and family caregiver concordance and/or discordance pertaining to formal support and care for family caregivers themselves. Although caregiver burden influenced how both family caregivers and patients approached decision-making, studies focused from the outset on patient care as opposed to formal supports for family caregivers aimed at alleviating burden of care. Family caregivers in palliative care can and do identify their own supportive and care needs, but few studies have focused on agreement or disagreement between patients and family caregivers on formal support and care available to or used by the family caregiver. Studies focused on patient and family caregiver concordance and/or discordance pertaining to formal support for family caregivers (eg, respite care and counselling) would further our understanding of what underpins concordance and/or discordance in decision-making between patients and family caregivers in palliative care.

**Strengths and limitations**

This review was limited to original peer-reviewed and full-text published studies between 2000 and 2021. However, including only original full-text studies allowed us to critically appraise the methodological quality of each piece of evidence included. We undertook an exhaustive search of multiple databases using a comprehensive and rigorous search strategy. We did limit the review to patients with clearly advancing illness and disease and our findings might not be transferrable to concordance and/or discordance between patients and family caregivers along the full illness trajectory. Systematic reviews on concordance and discordance between patients and family caregivers in palliative care along the full illness trajectory, or more specifically at key points prior to the advanced stages of patient illness, would further our understanding of relational decision-making between patients and family caregivers in palliative care. More longitudinal qualitative studies on concordance and discordance in decision-making between patients and family caregivers would also illuminate further how patients and family caregivers in palliative care accommodate each other’s preferences for and decisions about care.

**CONCLUSIONS**

Multiple studies in the last two decades have reported on factors associated with concordance and/or discordance in decision-making between patients and family caregivers in palliative care. Concordance and discordance between patients and family caregivers are shaped by multiple factors including family caregiver burden, pre-existing familial roles and relations, quality of communication between patients and family caregivers, patient and family caregiver knowledge of and judgements about care, patient and family caregiver awareness of each other’s preferences for care and how accepting (or not) patients and family caregivers are of end-of-life care. Few studies have focused on how patients and family caregivers manage discordance, but there is evidence that planning future care or simply discussion about patient future care can foster consensus between patients and family caregivers. Further investigation of how patients and family...
caregivers manage discordance in decision-making and how healthcare professionals can best support or facilitate this is needed. We have identified key factors and/ or processes which help explain how discordance and discordance manifest and function between patients and family caregivers in decision-making in palliative care. The findings of the review serve to focus future research on patient and family caregiver interdependence in decision-making in palliative care.
